FKL Series Specifications

Temperature Differential:

$\Delta 140^{\circ}\text{F}$ (standard rotor), $\Delta 210^{\circ}\text{F}$ (high temp. rotor)

Pump Housing Material:

316L stainless steel

Rotor Material:

808 non-galling stainless steel

optional: 316L stainless steel

Rotor Cap and Bolt Material:

316L stainless steel

Pump Cover Material:

316L stainless steel

Pump Shaft Material:

316L stainless steel

Product Contact Surface Finish:

32 Ra

optional: 25 Ra, 20 Ra, 15 Ra & electropolish (except 808 alloy rotors)

Fittings (Suction/Discharge):

1.5"–6"

optional: rectangular inlet available on FKL 50 - FKL 400

Fitting Style:

Sanitary clamp (FKL 15 – FKL 250)

300# flange (FKL 400 – FKL 600)

optional: many others available

Seal Type:

Single mechanical, double mechanical, aseptic double mechanical

Single O-ring and double O-ring (available on FKL 15–FKL 250 only)

Seal Flush Requirements:

Double seals only, 3–12 gallons per hour at 1–2 psi (60 psi maximum)

Mechanical Seal Face Materials (Stationary/Rotating):

Carbon / Chrome oxide coated stainless steel

optional: Silicon carbide / Silicon carbide

optional: Chrome Oxide / Silicon carbide

Elastomer Materials:

Cover Gasket–Buna; Seal O-rings–Viton

optional: many others available

Gearbox Material:

Cast iron / zinc plated / painted (Epoxy)

Gearbox Lubrication:

SAE 15W40 oil

Base Plate:

304 Stainless Steel with adjustable legs

FKL/FL II Special Pump Options

Rectangular Inlet

On many models (FKL 50–400, FL II 75–100), a rectangular inlet is offered to enhance the pump's ability to handle very viscous products. The large dimensional opening minimizes buildup of product at the inlet which promotes flow into the pump. Performance is maintained even when pumping very viscous materials because inlet restrictions are greatly reduced, thereby maintaining high volumetric efficiencies. Rectangular inlets match industry standards.

Rectangular Inlet Design

IL-0735
8/14/00

High Temperature Rotors

Positive pump efficiency depends upon maintaining close internal clearances between the rotors and the pump housing. These clearances are not a problem until higher temperatures cause the shaft and rotors to expand inside the pump housing. If the proper measures are not taken, this expansion can result in rotor to cover or even rotor to housing damage.

To counteract this effect, Fristam Pumps offers a high temperature rotor. This rotor leaves greater clearances throughout the pumping cavity.

High temperature rotors are specified for pumps that are cleaned or steamed at elevated temperatures, although process conditions may be cooler.

“Chocolate” Rotors

Specially machined rotors are available to produce the larger gaps required to pump chocolate and certain other viscous and abrasive products. Usage of these rotors should be discussed with the Fristam factory, in order to assure their proper application.

Clip Tip Rotors

Specially designed rotor which allows larger hard particulates to be pumped without damaging the rotor.

Single Lobe Rotors

The single lobe option is offered for products containing large solids. At low speeds, a single lobe rotor can handle the large particles more gently.

Thermal Siphon

Self contained seal flushing system for applications where water can not be used as a flushing liquid.

Single Lobe Rotor Design (FL II)

IL-0733
8/14/00

Aseptic Design (FKL only)

Aseptic designs are available for most of the FKL models. All of the dynamic and static sealing surfaces are steam traced to ensure product sterility.

Electropolish

Electropolish, an electrochemical process, provides additional smoothing, cleaning and passivation of pump surfaces. It is generally used in conjunction with high polish to produce extremely smooth product surfaces. Like high polish, the electropolish process removes some material and can produce a slight reduction in pump performance when pumping low viscous products.

Note: FKL 808 (standard) rotors cannot be electropolished. The chemical process adversely affects the non-galling alloy of which they are constructed.

High Grit Polish

25 Ra (180 grit), 20 Ra (240 grit), and 15Ra (320 grit) internal surface finishes are options offered for those applications requiring extremely smooth product surfaces. To accomplish this, additional material is removed from standard internal surfaces using finer grit abrasives. The removal of material will open the gaps between components slightly and increase slip. Some reduction of performance will result when pumping low viscosity fluids.

Tungsten Carbide Coating

Coating sprayed on to pump interior which will allow the pump to have a greater life when pumping abrasive products.

Kolsterizing

A hardening process for SS components which greatly increases the metal's resistance to wear from abrasive products.

Pressure Relief Cover

Fristam offers a spring loaded Teflon diaphragm pressure relief cover for customers that require a safety valve.

Degassing Cover (FKL only)

Exclusively for the baking industry, Fristam offers an optional degassing cover to vent the natural gases that are produced in dough. When used with Fristam's heavy-duty FKL Series positive displacement pump this feature gives the dough a finer texture and greater uniformity. Applications include transferring from a dough trough to a bun or bread divider or continuous conveyor belt.

Jacketed Cover (FKL)

For applications that require either a heating or cooling jacket to maintain the products state, Fristam Pumps can provide a jacketed cover. This jacketed cover is applied directly over the existing cover simply by using longer housing studs. The jacketed cover is constructed of 304 Stainless Steel.

Jacketed Cover (FKL)

Jacketed Housing and Cover

For applications that require either a heating or cooling jacket to maintain the products state, Fristam Pumps can provide a jacketed housing and/or cover. On the FL II pumps, the jacket is integral to the housing and/or cover. The jacketed cover is constructed of 304 Stainless Steel.

Jacketed Housing and Cover (FL II)

PD Pump Seal Option Guide

Mechanical Seal or O-ring Seal?

O-ring seals are recommended for applications where the pump will be regularly disassembled for cleaning.

Single or Double Seal?

Double seals are recommended for applications involving abrasive and/or sticky products and/or vacuum conditions of more than 12" Hg.

Material Options

Carbon vs. Chrome oxide-coated 316L SS: recommended for simple transfer applications

Chrome oxide-coated 316L SS vs. Silicon carbide: recommended for more difficult applications with pressure spikes, high viscosity (over 1,000 cps), or sticky (sugar-based) products

Silicon Carbide vs. Silicon carbide: recommended for the pharmaceutical industry and applications with high sodium concentrations

Positive Displacement Pump Basics

A. Definitions and Terms

Density

Density is the mass of a substance per unit volume. Generally, we express density in units of pounds per cubic inch.

Specific Gravity

Specific gravity is used to compare the density of a product to the density of water. The specific gravity of a product is expressed as its density divided by the density of water. This number will have no units, because it is simply a ratio.

Brix

Also called degrees Brix (°Brix), it is a hydrometer scale for sugar solutions. It is expressed as grams of soluble solids per 100g of liquid and is temperature corrected. Sugar content is approximately proportional to the °Brix value, with sugars contributing 55 to 75% of the °Brix.

Viscosity

Viscosity is a measurement of a product's resistance to flow. Low viscosity products (e.g. water) have little resistance to flow, while higher viscosity products have a greater resistance to flow. It is key to positive pump sizing and operation because it affects slip within the pump as well as the pressure required to overcome frictional loss in the lines. The product's resistance to flow produces system backpressure and heat. It will be explained later that the increased resistance to flow can be seen in the relationship between the frictional pressure loss (psi / foot tubing), flow rate (gpm), and product viscosity (cps) in the Friction Loss curves. It will also be explained that this same resistance to flow, by higher viscosity products, can be seen in reduced product slip inside the pump.

Newtonian vs. Non-Newtonian Fluids

A Newtonian fluid will have the same viscosity whether or not it is in motion. Examples of this type of fluid would be water and high fructose corn syrup (HFCS). A non-Newtonian fluid will have a different viscosity depending on the velocity of its flow. The majority of fluids are of this type, some examples would be ketchup, orange juice concentrate and shampoo.

Thixotropic Fluids

A thixotropic fluid is a type of non-Newtonian fluid that will become less viscous as the shear rate increases. This is also known as shear thinning, ketchup is a good example of this type of fluid. While the product is static, or standing still, the viscosity can be very high. As the fluid begins to flow it becomes less viscous and starts to run like water. After it sits again, it becomes very viscous. This thinning is due to shear in the fluid. As the fluid begins to move, the molecules will slide over each other and require less force to stay in motion. This force causes a shear stress in the fluid.

Apparent Viscosity

As previously explained, non-Newtonian fluids have less viscosity in motion, than at rest. The viscosity of a product in motion is known as its apparent viscosity. When a non-Newtonian fluid is in motion the apparent viscosity should be used for calculating the pressure drop. The apparent viscosity can be measured using a viscometer and plotting the results as a “Viscosity vs. Shear Rate” curve. This curve can be used with a shear rate curve for the tubing that is used in the system, to determine the apparent viscosity.

1. Find the product's flow rate (75 gpm) on the “Flow Rate vs. Shear Rate” curve for tubing.

2. Draw a line to the right until it intersects the 3" tubing diameter.

3. Follow the line down to find the shear rate. Shear rate=125

4. Find the shear rate on the “Viscosity vs. Shear Rate” curve for the product.

5. Move up until you intersect the line.

6. Move left to find the apparent viscosity. Apparent viscosity = 1500 cps.

Figure 1

Figure 2

Atmospheric Pressure

Atmospheric pressure is the force exerted by the weight of the atmosphere. At sea level, the average atmospheric pressure is 14.7 pounds per square inch (psia). Refer to Table 2 for the average atmospheric pressure at different elevations.

Gauge Pressure

Gauge pressure is the pressure read on a gauge installed in a system. At sea level the average atmospheric pressure is 14.7 psia, this would be equal to 0 psi gauge pressure. This is measured in units of pounds per square inch gauge or psig.

Table 2: Average Absolute Atmospheric Head

Altitude Above Sea Level (feet)	Atmospheric Pressure	Inches of Hg
0	14.7	29.9
500	14.4	29.4
1,000	14.2	28.9
1,500	13.9	28.3
2,000	13.7	27.8
3,000	13.2	26.8
4,000	12.7	25.9
5,000	12.2	24.9
6,000	11.7	24.0
7,000	11.3	23.1

Absolute Pressure

Absolute pressure is calculated by adding the atmospheric pressure to the gauge pressure. This is measured in units of pounds per square inch absolute or psia.

Static Pressure (Head)

Static pressure is the pressure exerted by a column of liquid above the centerline point of measurement.

$$p_s = (Z / 2.31) \times sg$$

$$p_s = \text{static pressure (psia)}$$

$$Z = \text{liquid level (ft)}$$

$$sg = \text{specific gravity (product)}$$

$$2.31 = \text{conversion factor (dimensionless)}$$

Vacuum

Vacuum refers to a pressure that is below the normal atmospheric pressure. If the tank feeding the inlet of a pump is at an absolute pressure less than atmospheric, the tank is said to be under vacuum. Vacuum is typically measured in units of inches of mercury (inches Hg). This number must be converted to psia, for NIPA calculations. For the conversion, see Table 6.

Vapor Pressure

The vapor pressure of a fluid is the pressure required at a given temperature to keep the fluid from turning to vapor. Water at 210°F has a vapor pressure of 14.123 psia. See Table 1 for the water vapor pressure.

NIPR – Net Inlet Pressure Required

NIPR is the pressure required by a pump to perform smoothly without cavitating. NIPR is measured in psia.

NIPA – Net Inlet Pressure Available

NIPA is the absolute pressure available at the inlet of the pump. NIPA is measured in psia.

Table 6: Pressure Conversions

212	14.696

Cavitation

Cavitation is the formation of vapor bubbles due to insufficient pressure at the inlet of the pump. High product temperature and/or low pressure on the inlet side of the pump can lead to insufficient pressure. Over time, cavitation can seriously damage a pump. Additional pressure energy would be required to supply the pump with the energy it requires to keep from cavitating. Four ways to increase NIPA are raise the level of the product in the tank, pressurize the tank, lower the pump or decrease the product temperature.

If the NIPR of the pump is greater than the NIPA in the system, the pump will cavitate. If the NIPR is less than the NIPA, the pump will not cavitate.

B. How a Positive Pump Operates

Positive Displacement Pump Operation (assuming sufficient NIPR)

Positive displacement pumps use two opposing, rotating elements (rotors) to displace product from the suction side of the pump to the discharge side of the pump. As the rotors rotate, the chamber formed between the rotors, housing and cover collects the product on the inlet side of the pump and carries the product to the discharge side of the pump.

Figure 6

Slip and Efficiency -

Positive pumps sometimes do not pump the full displacement for which they are rated because of a phenomenon called slip. To allow a positive pump's rotors to rotate, small clearances must be maintained between the rotors and housing. At lower viscosities these clearances allow some product to slip from the discharge side to the inlet side as the pump operates. The product that slips by will partially fill the inlet cavity. This amount of product must be "repumped" preventing the pump from reaching its full rated capacity and decreasing its volumetric efficiency.

- Internal clearances – The tighter the clearances, the less slip occurs.
- Viscosity – The amount of slip varies inversely with viscosity. The thicker the product, the less slip will occur. This reduction in slip eventually reaches a point called “zero slip”.
- Zero slip – Zero slip is the point at which the product is thick enough that it will no longer flow past the rotors. This point varies depending upon the internal clearances of the pump. The FKL reaches zero slip at 200 cps and the FL II achieves it at 500 cps. At these points the amount of differential pressure no longer becomes a factor.

Volumetric Efficiency = Actual Flow/Flow at Zero Slip

Full volumetric efficiency is achieved on all products with viscosities above the zero slip point.

Actual flow for products between one and the zero slip point will depend on the interaction of product viscosity and the differential pressure. At a constant product viscosity below zero slip, increasing the discharge pressure increases the product slip. At a constant discharge pressure, decreasing the product viscosity increases the product slip.

For products with a viscosity between 1 and 200 cps for the FKL and between 1 and 500 cps for the FL II the flow rate is dependent on the product viscosity and the differential pressure. At a constant product viscosity below zero slip, increasing the discharge pressure increases the product slip. At a constant discharge pressure, decreasing the product viscosity increases product slip. As the slip increases, the volumetric efficiency of the pump decreases because the full volume of the suction chamber is not available for new product.

$$\text{Slip} = (\text{Flow @ 0 psi}) - (\text{Flow @ 10 psi})$$

$$\text{Slip} = 100 \text{ gpm} - 70 \text{ gpm}$$

$$\text{Slip} = 30 \text{ gpm}$$

$$\text{VE} = 70\%$$

Figure 8 shows the effect that increasing the discharge pressure has on slip and volumetric efficiency. At 0 psi, the volumetric efficiency is 100%. As the pressure increases, product slips from the discharge side of the pump to the suction

$$\text{Volumetric Efficiency} = \frac{\text{Flow @ 10 psi}}{\text{Flow @ 0 psi}}$$

$$\text{VE} = \frac{70 \text{ GPM}}{100 \text{ GPM}} \times 100$$

Figure 9

1265000223
1/21/05

side.

Figure 9 shows that as product viscosity increases, slip decreases. As product slip decreases, volumetric efficiencies increase. At 200 cps the slip is zero and volumetric efficiency is 100%, assuming that the net inlet pressure of the pump is satisfied. At 200 cps, the zero psi pressure line is used for sizing the FKL.

Differential Pressure

The differential pressure that the pump must generate is key to sizing. Differential pressure is the total pressure against which a pump must work. Generally the suction pressure is negligible and the discharge pressure makes up nearly all of the differential pressure. If the suction gauge pressure is positive, the differential pressure across the pump is the discharge pressure minus the suction gauge pressure.

$$\text{Differential Pressure (psi)} = \text{Discharge Pressure (psi)} - \text{Suction Pressure (psi)}$$

The pressure gradient inside the pump shows that the positive pressure on the suction side (Figure 10) of the pump assists the rotor movement and reduces the product slip inside the pump. Pressurized tanks and product levels above the pump on the suction side contribute to positive suction pressures.

The pressure gradient inside the pump shows that the negative pressure on the suction side (Figure 11) of the pump pulls against the movement of the rotors and increases product slip inside the pump. A vacuum drawn on a tank and frictional losses in inlet piping contribute to negative suction pressures.

1265000472
Rev A1265000473
Rev A

Work Horsepower (WHp)

The power required to pump the product through a system. This is based on the pump speed and the pressure against which it is working.

Viscosity Horsepower (VHp)

The power required to move product through the pump. This is based on the pump speed and the viscosity of the product as it passes through the pump. The measurement is take with zero backpressure on the pump.

C. Frictional Losses through Sanitary Tubing

Friction loss is the loss of pressure energy through the interaction between the product and the tubing. The higher the product viscosity, the more pressure energy is lost through friction. This manual contains six graphs in Section III that can be used to calculate the system pressure drop through 1 ½", 2", 2 ½", 3", 4" and 6" tubing. Use the product's apparent viscosity and required flow rate to determine the frictional pressure drop through 1 foot of tubing, then multiply by the length of tubing in your system to obtain the total tubing frictional loss.

Examples 1, 2 and 3 show the effect of product viscosity and tubing size on frictional loss.

Example 1 – Determine the pressure loss resulting from 50 gpm of water at 1 cps flowing through 100 ft. of 1 ½" tubing. (see figure 14)

Directions:

- 1) Locate the product viscosity on the horizontal axis.
- 2) Move up vertically until you intersect the system flow rate.
- 3) Move horizontally and record the pressure loss in psi / foot tubing.

Given:

$$p_f = \text{tubing frictional loss (psi)} = f \times L$$

$$f = \text{frictional pressure loss (psi/ft tubing)}$$

$$L = \text{tubing length (ft)}$$

Refer to figure 14:

$$f = 0.1 \text{ psi/ft}$$

$$L = 100 \text{ ft}$$

$$p_f = 0.1 \text{ psi/ft} \times 100 \text{ ft}$$

$$p_f = 10 \text{ psi}$$

Example 2 – Now determine the pressure loss resulting from a flow rate of 50 gpm of 300 cps product flowing through 100 ft. of 1 ½" tubing.

$$f = 1.1 \text{ psi/ft}$$

$$L = 100 \text{ ft}$$

$$p_f = 1.1 \text{ psi/ft} \times 100 \text{ ft}$$

$$p_f = 110 \text{ psi}$$

Increasing the product viscosity from 1 cps to 300 cps increases the frictional pressure losses from 0.1 psi/ft to 1.1 psi/ft.

Figure 14 - Example 1 & 2 -

Pressure loss curve - 1 ½" tubing

Example 3 – (see figure 15) Increasing the tube size will reduce pressure loss through the piping system. A 300 cps viscosity product flowing at 50 gpm through 1 ½" tubing will develop 110 psi of system backpressure. Now repeat the example using 2" tubing and compare the result.

$$f = 0.32 \text{ psi/ft}$$

$$L = 100 \text{ ft}$$

$$p_f = 0.32 \text{ psi/ft} \times 100 \text{ ft}$$

$$p_f = 32 \text{ psi}$$

Increasing the tubing diameter from 1 ½" to 2" decreases the pressure loss by 0.78 psi / foot of tubing.

Figure 15 - Example 3 -

Pressure loss curve - 2" tubing

D. Calculating System Pressure

Refer to the pump inquiry sheet and use the system components specified to calculate the discharge and suction pressures of the system.

Discharge Tubing

Misc. _____

1. Total Discharge Pressure Losses

Several factors will go into calculating the total discharge pressure of the system. In our example, we must calculate the frictional losses resulting from 200 cps product flowing through 100' of 1 ½" tubing and three elbows at 50 gallons per minute. The elevation change of ten feet must also be included in the discharge pressure calculation.

Static Pressure

Determine the static pressure resulting from the elevation change from the centerline of the pump to the discharge of the system

p_s = static pressure (psi)

Z = liquid level (ft) = 12' – 2'

sg = specific gravity = 1.35

$p_s = (Z / 2.31) \times sg$

$p_s = (10 / 2.31) \times 1.35$

$p_s = 5.84$ psi

Frictional Loss – Tubing

Determine the frictional loss through 1 ½" discharge tubing.

Refer to the Friction Loss curves to determine the friction loss resulting from 50 gpm of 200 cps product through 100' of 1 ½" tubing.

- 1) Locate 200 cps on the horizontal axis of the chart.
- 2) Move vertically until you intersect the 50 gpm flow rate line.

- 3) Move horizontally and record the pressure loss in psi / foot of tubing.

p_f = tubing frictional loss (psi)

f = friction factor = 0.7 psi / ft

L = total length of tubing (ft) = 100 ft

$p_f = f \times L$

$p_f = 0.7 \times 100$

$p_f = 70$ psi

Figure 17 - Pressure loss curve - 1 ½" tubing

Frictional Loss – Elbows and Tees

To calculate the frictional loss for the fittings, we will first convert the fittings into an equivalent length of tubing. Refer to Table 3 to determine the equivalent length of the three elbows in the discharge tubing. Note that as the viscosity increases, the loss goes down for any one tubing size. This happens because the higher viscosity product flows through the fitting with less turbulence.

Next, we will calculate the pressure loss over that length of tubing.

$$p_e = \text{frictional loss in fittings (psi)} = L_e \times n \times f$$

$$L_e = \text{equivalent length / elbow (ft/elbow)} = 2 \text{ ft/elbow}$$

$$n = \text{number of elbows} = 3$$

$$f = \text{frictional pressure loss (psi/ft)} = 0.7 \text{ psi/ft}$$

$$p_e = L_e \times n \times f$$

$$p_e = 2 \times 3 \times 0.7$$

$$p_e = 4.2 \text{ psi}$$

Table 3: Elbow Length Equivalent (feet)

B 200 cps					
Size		1 to 150 cps	150 to 1,500 cps	1,500 to 15,000 cps	15,000 to 100,000 cps
A. 1 1/2 tubing	1 1/2	2.5	2	1.4	0.7
	2	3.5	2.3	1.8	0.8
	2 1/2	4	2.5	2	1
	3	5	3.5	2.5	2
	4	6	4.5	3	2
	6	9	6.5	4	2.25

Figure 18 - Calculating the equivalent length/elbows (L_e). In the previous step, we learned the discharge tubing is 1 1/2" and the product is 200 cps.

Total Frictional Pressure Loss

Combine the tubing frictional loss and the frictional loss in fittings to find the total frictional pressure loss.

$$p_t = \text{total frictional loss (psi)} = p_f + p_e$$

$$p_f = \text{tubing frictional loss (psi)} = 70 \text{ psi}$$

$$p_e = \text{frictional loss in fittings (psi)} = 4.2 \text{ psi}$$

$$p_t = p_f + p_e$$

$$p_t = 70 + 4.2$$

$$p_t = 74.2 \text{ psi}$$

Total Discharge Pressure Losses

Combine the total frictional pressure loss and the static pressure to find the total discharge pressure loss.

$$p_d = \text{total discharge pressure (psi)} = p_t + p_s$$

$$p_t = \text{total frictional loss (psi)} = 74.2 \text{ psi}$$

$$p_s = \text{static pressure (psi)} = 5.84 \text{ psi}$$

$$p_d = p_t + p_s$$

$$p_d = 74.2 \text{ psi} + 5.84$$

$$p_d = 80.04 \text{ psi}$$

2. Pump Suction – Calculating NIPA

The NIPA (net inlet pressure available) should be calculated to determine the pressure energy available to the pump. The NIPA of the system should be compared to the NIPR (net inlet pressure required) of the pump model being considered to execute the specific duty. If the NIPA of the system is less than the NIPR for the pump, the system should be modified to increase the NIPA or a pump model requiring less NIPA should be considered.

Atmospheric Pressure

Refer to Table 2 to determine the average atmospheric pressure.

The altitude above sea level is 4,000 ft.

$$p_i = 12.7 \text{ psia}$$

Static Pressure

The total height above the centerline of the pump inlet is 5 feet (Figure 20).

$$p_i = \text{static pressure (psi)}$$

$$Z = \text{total height (ft)} = 5 \text{ ft}$$

$$\text{sg} = \text{specific gravity} = 1.35$$

$$p_i = (Z / 2.31) \times \text{sg}$$

$$p_i = (5 / 2.31) \times 1.35$$

$$p_i = 2.92 \text{ psi}$$

Table 2: Atmospheric Pressure

Altitude Above Sea Level (feet)	Atmospheric Pressure	Inches of Hg
0	14.7	29.9
500	14.4	29.4
1,000	14.2	28.9
1,500	13.9	28.3
2,000	13.7	27.8
3,000	13.2	26.8
4,000	12.7	25.9
5,000	12.2	24.9
6,000	11.7	24.0
7,000	11.3	23.1

Figure 19 - Finding the Atmospheric Pressure.

Table 6: Vapor Pressure

Water Temperature (°F)	Vapor Pressure (psia)
100	0.949
110	1.275
120	1.692
130	2.223
140	2.889
150	3.718
160	4.741
170	5.992
180	7.511
190	9.340
200	11.526
210	14.123
212	14.696

Figure 21 - Finding the vapor pressure using the temperature.

Vapor Pressure

Determine the vapor pressure for water by looking at Table 1.

Since our product does not have a vapor pressure table, most do not, we will use the table for water. The table for water is similar to what a table for another fluid would be like (Figure 21).

The product temperature is 150°F.

$$\text{vp} = 3.718 \text{ psia}$$

Frictional Loss – Tubing

Refer to the pressure loss curves in Section III to determine the frictional loss in psi / foot of tubing for a 200 cps product traveling at 50 gpm through 6 feet of 2” tubing.

p_t = tubing frictional loss (psi)

f = frictional pressure loss (psi/ft tubing) = 0.21 psi/ft (Figure 22)

L = tubing length (ft) = 6 ft

$$p_t = f \times L$$

$$p_t = 0.21 \times 6$$

$$p_t = 1.26 \text{ psi}$$

Frictional Loss - Elbows and Tees

Refer to Table 3 for the equivalent length of tubing for 200 cps product flowing through one 2” elbow.

p_e = frictional loss in fittings (psi)

L_e = equivalent length / elbow (ft/elbow) = 2.3 ft (Figure 23)

n = number of elbows = 1

f = frictional pressure loss (psi/ft) = 0.21 psi/ft

$$p_e = L_e \times n \times f$$

$$p_e = 2.3 \times 1 \times 0.21$$

$$p_e = 0.48 \text{ psi}$$

Total Frictional Losses

Combine the tubing frictional loss and the frictional loss in fittings, to find the total frictional loss.

p_t = total frictional loss (psi)

p_t = tubing frictional loss (psi) = 1.26 psi

p_e = frictional loss in fittings (psi) = 0.48 psi

$$p_t = p_t + p_e$$

$$p_t = 1.26 + 0.48$$

$$p_t = 1.74 \text{ psi}$$

		B. 200 cps	
	Size	1 to 150 cps	150 to 1,500 cps
A. 2" tubing	1 ½	2.5	2
	2	3.5	2.3
	2 ½	4	2.5
	3	5	3.5
	4	6	4.5
	6	9	6.5

Figure 23- Calculating the equivalent length by the tubing size and cps.

NIPA

Net Inlet Pressure Available

p_a = atmospheric pressure (psia)

p_s = static pressure (psi)

vp = vapor pressure (psi)

p_f = total frictional loss (psi)

$$NIPA^* = p_a + p_s - vp - p_f$$

$$NIPA = 12.7 + 2.92 - 3.718 - 1.74$$

$$NIPA = 10.162 \text{ psia}$$

* NIPA is calculated in absolute pressure (psia)

3. Differential Pressure

For proper pump selection, the differential pressure should be calculated. When calculating the differential pressure, use the gauge pressure at the inlet and not the NIPA.

The values used in these examples were calculated above.

Gauge Pressure at Inlet

p_i = gauge pressure at inlet (psi)

p_s = static pressure (psi) = 2.92 psi

p_f = total frictional loss (psi) = 1.74 psi

$$p_i = p_s - p_f$$

$$p_i = 2.92 - 1.74$$

$$p_i = 1.18 \text{ psi}$$

Differential Pressure

P = differential pressure

p_d = total discharge pressure (psi) = 80.04 psi

p_i = gauge pressure at inlet (psi) = 1.18 psi

$$P = p_d - p_i$$

$$P = 80.04 - 1.18$$

$$P = 78.86 \text{ psi}$$

E. Positive Displacement Pump Cleaning Recommendations

Some recommendations for cleaning PD pumps are as follows:

When you are running products or cleaning solutions with different temperatures, you need to allow enough time for all of the wetted components inside the pump to reach a steady-state temperature before you start the pump. If your process does not allow you to stop the pump during this transition, you need to install rotors that provide larger clearances. Note: that the clearances inside the FKL pump are extremely small.

If the process lines are to be cleaned with the pump, use a by-pass loop around the pump during the CIP mode to maintain pipe velocity. Once the wetted components are at a steady temperature, the pump can be started and run around 100 RPM with a backpressure of at least 10 PSI. As the product viscosity increases, the required backpressure may need to be increased as well.

Contact Fristam if you have any questions.

Selecting a Positive Displacement Pump

Using Performance Curves

Choosing a Pump Series

A. Gather all application information including product nature, viscosity, temperature, NIPA, flow rate and pressure loss.

B. Decide what series pump to use, FL II or FKL. For simple applications the more economical FL II pump will work, when the duty exceeds the capabilities of this pump the FKL should be applied.

The FKL and FL II Product Lines – Better Choices for Better Performance

To best match the broad range of positive displacement pump applications Fristam provides two product lines, the FKL and the FL II. While sharing many similarities the pumps are fundamentally different in design.

The FKL is a circumferential piston pump, meaning that its rotors run in a channel described by the pump housing and built-in internal hubs. The purpose of this design is to achieve high performance by maintaining tighter clearances and restricting product slip within the pump. The design produces higher pressures, the ability to self-prime and the capability of handling more difficult products and applications.

The FL II is a rotary lobe pump. Rotary lobes use the movement of two lobes in a pumping chamber to accomplish the pumping action. This style of pump is designed for standard duty applications.

Choosing Between the FKL or FL II

The FKL can be selected for any application within the capabilities of it or the FL II. Within its range, the FL II will often be a more attractive selection because of its economy and simplicity. The FL II should be considered for applications within the following parameters.

- Pressures to 170 psi
- Viscosities to 50,000 cps
- Flooded suction with at least 7 psia available
- Mechanical seals required
- 316L stainless steel rotors required
- Product is low to moderately shear sensitive

Selecting a Pump Size

Use the composite curves to make your initial pump selection.

1. Locate the product viscosity on the horizontal axis (1).
2. Locate the required flow rate on the vertical axis (2).
3. Determine the intersection between the flow rate and product viscosity (3).
4. Select a pump model above the intersection (3).

When selecting, keep in mind that it is best to run a positive displacement pump at no more than 400 to 500 rpm. The lower speeds reduce seal wear, extend pump life, reduce suction pressure requirements and produce quieter operation. The composite curves are based on the maximum speed of the pumps; therefore, the model selected will usually be one or two above the duty point.

For example: For a flow rate of 50 gpm and a product with a viscosity of 200 cps, the model directly above the duty point is an FL II 75L.

Figure 24

However, if we look at the individual curve for this pump we will see that it would have to run above the desired speed range. Therefore, to maintain the desired speed range, we will select the next larger model, an FL II 100S.

Viscosity Adjustment

Viscosity adjustment is not necessary for products with a viscosity above the pumps zero-slip point. Also viscosity adjustment is not necessary for products at 1 cps, since the curves are calculated at 1 cps. The zero slip point is 500 cps for the FL II and 200 cps for the FKL. Speed must be increased for products with a viscosity below the zero slip point in order to deliver the required flow rate. This is the most confusing part of PD selection. It is necessary because pump performance will vary for viscosities below the zero slip point. The adjustment converts the slip factor for different viscosity products into an equivalent based on water.

1. Locate the calculated differential pressure on the vertical axis (1).
2. Follow the pressure line, down and to the right, until it intersects (3) the product viscosity (2).
3. Record the adjusted pressure value on the vertical axis (4). This value is the pressure that will be used on the slip curve.

High Temperature Rotor Adjustment

For applications that fall below the zero slip point and require high temperature rotors, another speed adjustment is necessary. The increased clearances produced by these rotors require this adjustment, to compensate for the additional slip they produce.

For any of the FL II pumps, use the curve below.

1. Locate the calculated differential pressure on the vertical axis (1).
2. Follow the pressure line, down and to the right, until it intersects (3) the product viscosity (2).
3. Read all the way to the left until you find the line representing the model that was selected (4).
4. Record the additional speed at the horizontal axis (5). This number will be added to the speed calculated for the pump.

Figure 26 - FL II High Temperature Rotor Correction Curve

Determining Pump Speed

To determine the pump speed:

1. Locate the required flow rate on the pump curve (1).
2. Move horizontally until you intersect the correct pressure (2). This will depend on the viscosity of the product. For products with a viscosity of 1 cps, the correct pressure line will be the differential pressure. For viscosities between 1 and 500 cps for the FL II pump, the correct line will be the viscosity-adjusted pressure. For viscosities above 500 cps for the FL II, the correct line will be 0 psi.
3. Move straight down until you intersect the horizontal axis (3).

Determining Horsepower Requirements

1. Determine the Work Horsepower (WHp).
Continue to move down until you intersect the differential pressure (4), not the adjusted pressure. Read the power off the vertical axis directly to the left (5).

2. Determine the viscosity horsepower (VHp).
Continue to move down (from the differential pressure point) until you intersect the product viscosity (6). Read the power off the vertical axis directly to the left (7).

3. Add these two numbers together to calculate the overall brake horsepower.

$$\text{BHp} = \text{WHp} + \text{VHp}$$

Figure 27

Net Inlet Pressure Required (NIPR)

Check the Net Inlet Pressure Required (NIPR) for the selected pump. For the FL II pumps, be sure that the NIPR is at least 7 psia. For the FKL, each pump has its own curve.

Determining Drive Torque Requirements

Calculate the application torque. The application torque will be used to help size the pump drive and the coupling used to connect the drive to the pump. Each of these components will have a maximum allowable torque and the application torque cannot exceed this.

$$T = (63,025 \times \text{BHp}) / \text{speed}$$

Figure 28: FKL 25 NIPR curve

Pump Selection Examples

Example 1

Water at 1 cps, 1.0 SG and 68°F

The duty will be 20 gpm @ 200 psi and the NIPA will be 4 psia

The pressure of this duty point exceeds the maximum of any of our FL II pumps and the NIPA is relatively low, therefore we will select a FKL pump for this application.

Look at the composite curve and select a model (as explained earlier).

The model that will work best is the FKL 50.

This duty will not require a viscosity or temperature adjustment since the product is at 1 cps. The actual slip line can be read off the curve.

Figure 29

1265000503
Rev B

Calculate the pump speed, horsepower and application torque.

For example 1, the FKL 50 requires 494 rpm to deliver 1 cps product at 20 gpm against 200 psi.

$$\text{BHp} = \text{WHp} + \text{VHp}$$

$$\text{BHp} = 6.1 + 0.4$$

$$\text{BHp} = 6.5$$

$$T = \text{Torque (in/lbs.)}$$

$$T = (\text{BHp} \times 63,025) / \text{speed}$$

$$T = (6.5 \times 63,025) / 494$$

$$T = 829 \text{ in-lbs}$$

Check the NIPR of the pump using Figure 30.

The NIPR is 2.7 psia, therefore the NIPA of 4 psia is more than enough. The final selection would be a FKL 50, running at 494 rpm with a 7.5 hp drive and having a torque of 829 in-lbs.

Figure 30

Figure 31

Example 2

High Fructose Corn Syrup at 5,000 cps, 1.32 SG and 38°F

The duty will be 100 gpm @ 250 psi and the NIPA will be 10 psia

The pressure of this duty point exceeds the maximum of any of our FL II pumps; therefore, we will select a FKL pump for this application. Look at the composite curve (Figure 32) and select a model (as explained earlier).

Figure 32

The model that will work best is the FKL 250. The FKL 150 is above the duty point, but the speed required is too high.

This duty will not require a viscosity or temperature adjustment.

Calculate the pump speed, horsepower and application torque. The speed can be calculated by dividing the flow rate by the displacement, or it can be found by reading the zero slip line on the slip chart.

Figure 33

For example 2, the FKL 250 requires 179 rpm to deliver 5,000 cps product at 100 gpm against 250 psi.

$$\text{BHp} = \text{WHp} + \text{VHp}$$

$$\text{BHp} = 17.5 + 5.0$$

$$\text{BHp} = 22.5$$

$$T = (\text{BHp} \times 63,025) / \text{speed}$$

$$T = (22.5 \times 63,025) / 179$$

$$T = 7,922 \text{ in-lbs}$$

Check the NIPR of the pump using the NIPR curve Figure 33.

The NIPA of 10 psi will be more than the 5.3 psi required for the FKL 250. The final selection would be a FKL 250, running at 179 rpm with a 25 hp drive and having a torque of 7,922 in-lbs.

Figure 34

Horsepower = Work Horsepower + Viscosity Horsepower

Example 3

Pie filling at 200 cps, 1.2 SG and 90°F

The duty will be 50 gpm @ 75 psi and the NIPA will be 10 psia

This is a simple application with a low duty point pressure and plenty of NIPA; therefore, we will select a FL II pump. Look at the composite curve (Figure 35) and select a model (as explained earlier).

The FL II 100S is above the duty point. We will not select the FL II 75L for this application, because we are trying to keep the pump speed below the 400 – 500 rpm range.

This duty will require a viscosity adjustment, but will not require a high temperature adjustment.

Following the viscosity adjustment procedure for the FL II pump, we determine the slip curve will be read on the 10 psi line.

The NIPA for the application is 10 psia, which is more than adequate for the FL II 100S.

Calculate the pump speed, horsepower and application torque.

For example 3, the FL II 100S requires 390 rpm to deliver 200 cps product at 50 gpm against 75 psi.

$$\text{BHp} = \text{WHP} = \text{VHP}$$

$$\text{BHp} = 4.2 + 1.2$$

$$\text{BHp} = 5.4$$

$$T = (\text{BHp} \times 63,025) / \text{speed}$$

$$T = (5.4 \times 63,025) / 390$$

$$T = 873 \text{ in-lbs}$$

The final selection would be a FL II 100S, running at 390 rpm with a 7.5 Hp drive and having a torque of 873 in-lbs.

Figure 37

Example 4

Vegetable Oil at 3 cps, 0.98 SG and 275°F

The duty will be 100 gpm @ 80 psi and the NIPA will be 10 psia

This is a simple application with a low duty point pressure and plenty of NIPA; therefore, we will select a FL II pump. Look at the composite curve (Figure 38) and select a model (as explained earlier).

The FL II 130S falls above the duty point and will fall within the preferred speed range.

This duty will require a small viscosity adjustment and a high temperature adjustment.

Following the viscosity adjustment procedure for the FL II pump, we determine the slip curve will be read on the 62 psi line.

Use the High Temperature Rotor Correction curve (Figure 40) to determine the speed adjustment. We will add 27 rpm to the speed, to compensate for the high temperature rotors.

1265000511
Rev A

1265000512
Rev A

The NIPA for the application is 10 psia, which is more than adequate for the FL II 130S.

Calculate the pump speed, horsepower and application torque.

For example 4, the FL II 130S requires 360 rpm to deliver 3 cps product at 100 gpm against 80 psi. We then need to add 27 rpm to the 360 rpm.

$$\text{BHp} = \text{WHp} + \text{VHp}$$

$$\text{BHp} = 10.0 + 1.5$$

$$\text{BHp} = 11.5$$

$$T = (\text{BHp} \times 63,025) / \text{speed}$$

$$T = (11.5 \times 63,025) / 387$$

$$T = 2,085 \text{ in-lbs}$$

The final selection would be a FL II 130S, running at 387 rpm with a 15 Hp drive and having a torque of 2,085 in-lbs.

6	9	6.5	4	2.25

Table 4: Tee Equivalent Length (feet)

Size	1 to 150 cps	150 to 1,500 cps	1,500 to 15,000 cps	15,000 to 100,000 cps
1 ½	9	6.5	4	2.25
2	12	8.5	6	2.7
2 ½	15	11	7.5	3.75
3	18	13	8	4
4	20	15	10	5
6	35	25	18	10

Table 5: Valve Equivalent Length (feet)

Size	1 to 150 cps	150 to 1,500 cps	1,500 to 15,000 cps	15,000 to 100,000 cps
1 ½	11	8	5.5	2
2	18	13	8	4
2 ½	20	15	10	5
3	27	20	14	7
4	33	25	17	10

Source: Tables 3 - 5 were created from Crane Co. Technical Paper No. 409. Data based on the chart are satisfactory for most applications.

Table 6: Conversion Factors and Helpful Formulas

Length				Flow			
Meters	x	3.281	= Feet	Pounds of Water / Hour	x	0.002	= GPM
Centimeters	x	0.394	= Inches	Pounds of Fluid / Hour	x	0.002 / SG	= GPM
Millimeters	x	0.0394	= Inches	Cubic Meters / Hour	x	4.4	= GPM
Inches	x	25.4	= Millimeters	Liters / Minute	x	0.264	= GPM
Mass				Viscosity			
Kilograms	x	2.2	= Pounds	Centipoise	x	1 / SG	= Centistokes
Gallons of Water	x	8.34	= Pounds	SSU	x	0.216	= Centistokes
Cubic Feet of Water	x	62.4	= Pounds	Saybolt Furol	x	2.16	= Centistokes
Pounds	x	0.454	= Kilograms	Redwood Standard	x	0.237	= Centistokes
Volume				Redwood Admiralty	x	2.34	= Centistokes
Liter	x	0.264	= Gallon	Engler-Degrees	x	7.45	= Centistokes
Cubic Feet	x	7.48	= Gallon	Ford Cup #4	x	3.76	= Centistokes
Pounds of Water	x	0.119	= Gallon	MacMichael	x	0.415	= Centistokes
Imperial Gallon	x	1.2	= Gallon	Stormer	x	2.81	= Centistokes
Gallon	x	3.785	= Liter	Power			
Pressure				T (in - lbs.) x RPM	/	63,025	= Horsepower
Feet of Water	x	0.433	= PSI	Kilowatts	x	1.341	= Horsepower
Inches of Mercury	x	0.491	= PSI	Metric Horsepower	x	0.9863	= Horsepower
Atmospheres	x	14.7	= PSI	Horsepower	x	0.746	= Kilowatts
Meters of Water	x	1.42	= PSI	Horsepower	x	42.44	= BTU / Minute
Bar	x	14.7	= PSI	$\frac{\text{GPM} \times \text{Head (ft. of water)} \times \text{SG}}{3960}$			= Liquid Hp
Kilo Pascals	x	0.145	= PSI	Efficiency			
Atmospheres	x	33.9	= Feet of Water	$\frac{\text{Liquid HP}}{\text{Brake HP}}$			= Efficiency
PSI	x	2.31	= Feet of Water	*Brake HP is read off the pump curve			
Inches of Mercury	x	1.13	= Feet of Water				
Meters of Water	x	3.28	= Feet of Water				
Temperature							
°C x 1.8	+	32	= °F				
°F - 32	x	0.555	= °C
